The application of servocontrolled mechanical-bearing-based precision motion stages (MBMS) is well-established in advanced manufacturing, semiconductor industries, and metrological applications. Nevertheless, the performance of the motion stage is plagued by self-excited friction-induced vibrations. Recently, a passive mechanical friction isolator (FI) has been introduced to reduce the adverse impact of friction in MBMS, and accordingly, the dynamics of MBMS with FI were analyzed in the previous works. However, in the previous works, the nonlinear dynamics components of FI were not considered for the dynamical analysis of MBMS. This work presents a comprehensive, thorough analysis of an MBMS with a nonlinear FI. A servocontrolled MBMS with a nonlinear FI is modeled as a two DOF spring-mass-damper lumped parameter system. The linear stability analysis in the parametric space of reference velocity signal and differential gain reveals that including nonlinearity in FI significantly increases the local stability of the system's fixed-points. This further allows the implementation of larger differential gains in the servocontrolled motion stage. Furthermore, we perform a nonlinear analysis of the system and observe the existence of sub and supercritical Hopf bifurcation with or without any nonlinearity in the friction isolator. However, the region of sub and supercritical Hopf bifurcation on stability curves depends on the nonlinearity in FI. These observations are further verified by a detailed numerical bifurcation, which reveals the existence of nonlinear attractors in the system.

Keywords: the LuGre friction model, precision motion stage, nonlinear friction isolator, stability analysis, Hopf bifurcation

1 Introduction

Motion stages provide high-speed and high-precision positioning in manufacturing and metrology-related processes, which include machining, additive manufacturing, and semiconductor fabrications [1–4]. Among magnetic-based, flexural-based, fluidic-based, and mechanical-bearing-based motion stages (MBMS), MBMS are more prominent in the industries due to their cost-effectiveness, high off-axis stiffness, wide ranges of motions, and easy-to-install feature [5]. The motion control of MBMS in different applications is commonly realized by using different servocontrollers [6–8]. However, it can lead to the problem of self-excited limit cycles in the tracking error caused by the sliding friction between contact surfaces, which is also known as friction-induced vibrations (FIV) [6,9–14]. The adverse effects of friction on the control performance include oscillations of stick-slip phenomena tracking errors and long settling times. Therefore, understanding the dynamics of self-excited friction-induced vibrations under different conditions is essential to mitigate tracking error oscillation, which leads to better motion stage performances.

Different controllers have been proposed to eliminate friction-induced vibrations. The fundamental concept of these controllers to suppress FIV is to counteract the friction force by providing an equal and opposite force and suppress these FIV. These controllers can be divided into three categories as (1) high-gain controllers, (2) model-based controllers, and (3) advanced controllers. The use of these controllers in compensating for the effect of friction is well-established in the literature [11,13,15–18]. However, the performance of these controllers can be limited by environmental noise in the case of high-gain controllers, model inaccuracy in the case of

model-based controllers, and low-performance computational/ actuator hardware in the case of advanced controllers.

Recently, a mechanical device known as the friction isolator (FI) was proposed as a more robust and efficient approach to mitigating self-excited friction-induced vibrations in the MBMS system [19,20]. Unlike conventional motion stages in which the bearings are rigidly installed to the table, the compliant motion stages adopt FI as motion-compliant joints between the bearings and the table, isolating the table from nonlinear frictional effects. For more design details of FI, readers are referred to Refs. [19,20]. Furthermore, parametric analyses on the motion stage with FI showed that with optimum design parameter selections, FI could increase the fixed-point stability region to allow the use of higher control gains and reduce the amplitudes of the control error limit cycles [21,22]. However, the above-mentioned studies analyzed the dynamics of an MBMS with linear FI only. Nevertheless, the mechanical design of FI can introduce nonlinear elements, which are significantly compared to the linear elements [19] and hence, need to be considered in the dynamics of compliant motion stages for optimum selection of control parameters. The present paper examines this problem and provides a framework for further analysis. For this, we extend the model proposed in Refs. [22] by introducing a nonlinear element in the system to take into account nonlinear FI. The preliminary linear stability analysis reveals that linear FI under-estimates the stability regime, and hence, it is desirable to consider nonlinearity in FI for a better selection of control parameters for steady operations. Furthermore, the nonlinear analysis using the analytical method, more specifically the method of multiple scales, reveals the existence of super and subcritical Hopf bifurcation in the system regardless of the presence of nonlinearity in FI. However, for the given value of system parameters, the region corresponding to supercritical bifurcation can be increased by properly selecting the nonlinear parameters.

The paper is arranged as follows. We outline the extended model of MBMS with nonlinear FI in Sec. 2. Later on, the linear stability

analysis of fixed-points is investigated in Sec. 3. This is followed by a detailed analysis of the current system in Sec. 4. Results and detailed discussions from the previous sections are presented in Sec. 5. Finally, some conclusions are drawn in Sec. 6.

2 Mathematical Formulation

To establish the effect of nonlinearity in the friction isolator and the contribution of various system parameters to linear and nonlinear instability of PD-controlled MBMS, a nonlinear two DOF model, illustrated in Fig. 1, is obtained by extending the linear model discussed in Ref. [22]. In this model, the precision motion stage is modeled as a rigid mass m_t, whereas the combined mass of the friction isolator and bearing is modeled as m_b. The nonlinear interactions between m_b and m_t are represented by a nonlinear spring with a stiffness function $K(.)$, and a linear damper with damping coefficient c_{fi}. Also, in this model, u_1 and $r(t)$ represent the output feedback control force from the PD controller and input reference/ set-point signal to the PD controller, respectively. Therefore, if $X_1(t)$ and $X_2(t)$ represent the position of MBMS and FI, respectively, then the equations of motion for the system are given by

$$m_t\ddot{X}_1 + K(X_1 - X_2) + c_{\text{fi}}(\dot{X}_1 - \dot{X}_2) = u_1 \quad (1a)$$

$$m_b\ddot{X}_2 - K(X_1 - X_2) + c_{\text{fi}}(\dot{X}_2 - \dot{X}_1) = -F_f \quad (1b)$$

In the above governing equations, the feedback force u_1 is defined as

$$u_1 = -k_p^*\beta - k_d^*\dot{\beta}_1 \quad (2)$$

where k_p^* is the proportional gain, k_d^* is the differential gain, β is the tracking error defined as the difference between the position and reference input, i.e., $\beta = X_1 - r$ and, F_f represents the friction force between the bearing and the support platform. For the current analysis, we use the LuGre friction model to represent the friction force between the surfaces as it incorporates hysteresis effects, premotion friction, and viscous friction altogether. Furthermore, the frictional force in the LuGre friction model relates to the relative velocity between the surfaces and on an internal state variable z, which can be interpreted as the average transverse deflection of microscopic asperities/bristles of the contact surfaces [23–26]. The friction force in the LuGre friction model is described by the following equation [23]:

$$F_f = \sigma_0^* z + \sigma_1^* \dot{z} + \sigma_2^* V_r \quad (3)$$

whereas z, the average asperity/bristle deflection, is determined by the following equation [23,27]:

$$\dot{z} = V_r - \frac{\sigma_0^*|V_r|}{G(V_r)}z = V_r\left(1 - \frac{\sigma_0^*\text{sgn}(V_r)}{G(V_r)}z\right) \quad (4)$$

In the above equations, V_r is the relative velocity between the contact surfaces, σ_0^* is the asperity/bristle's stiffness, σ_1^* is the damping coefficient of the asperity/bristle, whereas σ_2^* is the friction due to viscosity between the contact surfaces, and $G(V_r) > 0$ is a positive valued function to define the Stribeck effect. In the current work, this positive valued function of relative velocity is chosen in the form of the following equation [27,28]:

Fig. 1 Schematic of the MBMS with nonlinear friction isolator

$$G(V_r) = f_C^* + \left(f_S^* - f_C^*\right)e^{-\bar{a}|V_r|} \quad (5)$$

where $\tilde{a}$ is the slope parameter. Now with the definition of friction force, Eq. (1) can be rewritten in terms of e as

$$m_t\ddot{\beta} + k_p^*\beta + k_d^*\dot{\beta} + g(\beta - \beta_b) + c_{\text{fi}}(\dot{\beta} - \dot{\beta}_b) = -m_t\ddot{v}_{rv} \quad (6a)$$

$$m_b\ddot{\beta}_b - g(\beta - \beta_b) + c_{\text{fi}}(\dot{\beta}_b - \dot{\beta}) = -(\sigma_0^*z + \sigma_1^*\dot{z} + \sigma_2^*V_r) - m_b\ddot{v}_{rv} \quad (6b)$$

In the above-modified equations of motion, β_b is defined as $\beta_b = X_2 - r$. Since earlier studies suggest that the nonlinearities involved with the LuGre friction model are primarily the combination of quadratic and cubic terms, we assume that the stiffness function involved with the friction isolator has a similar nonlinear restoring force characteristic as our primary system, i.e., the combination of quadratic and cubic terms [29,30]. Therefore, provided that k_{fl}^*, k_{fq}^*, and k_{fc}^* represent the linear, quadratic, and cubic stiffness of FI, respectively, Eq. (6) can be written as

$$m_t\ddot{\beta} + k_p^*\beta + k_d^*\dot{\beta} + k_{fl}^*(\beta - \beta_b) + k_{fq}^*(\beta - \beta_b)^2 + k_{fc}^*(\beta - \beta_b)^3 + c_{\text{fi}}(\dot{\beta} - \dot{\beta}_b) = -m_t\ddot{\beta} \quad (7a)$$

$$m_b\ddot{\beta}_b + k_{fl}^*(\beta_b - \beta) - k_{fq}^*(\beta_b - \beta)^2 + k_{fc}^*(\beta_b - \beta)^3 + c_{\text{fi}}(\dot{\beta}_b - \dot{\beta}) = -(\sigma_0^*z + \sigma_1^*\dot{z} + \sigma_2^*V_r) - m_b\ddot{\beta}_b \quad (7b)$$

Next, we define the following scales and nondimensional parameters in the system.

$$x = \frac{\beta}{X_0}, \quad x_b = \frac{\beta_b}{X_0}, \quad \tilde{z} = \frac{z}{X_0}, \quad X_0 = \frac{g}{\omega_p^2}, \quad \omega_p = \sqrt{\frac{k_p^*}{m_t}},$$

$$\tau = \omega_p t, \quad \zeta = \frac{k_d^*}{2m_t\omega_p}, \quad v_r = \frac{V_r}{X_0\omega_p},$$

$$\sigma_0 = \frac{\sigma_0^*}{m_t\omega_p^2}, \quad \sigma_1 = \frac{\sigma_1^*}{m_t\omega_p}, \quad \sigma_2 = \frac{\sigma_2^*}{m_t\omega_p}, \quad f_c = \frac{f_c^*}{m_tX_0\omega_p^2},$$

$$f_s = \frac{f_s^*}{m_tX_0\omega_p^2}, \quad a = \tilde{a}\omega_pX_0,$$

$$\kappa = \frac{c_{\text{fi}}}{2m_t\omega_p}, \quad k_r = \frac{k_{fi}}{k_p}, \quad m_r = \frac{m_t}{m_b}, \quad k_{rq} = \frac{k_{fq}^*X_0}{k_p^*}, \quad k_{\text{rc}} = \frac{k_{fc}^*X_0^2}{k_p^*} \quad (8)$$

In the above nondimensional scales, g is the acceleration due to gravity. Using the above-mentioned scales and nondimensional parameters, the governing equations of motion (Eqs. (7), (4), and (5)) can be nondimensionalized for the case of constant reference velocity, i.e., $\ddot{v}_{rv} = 0$, to get

$$\ddot{x} + 2\zeta\dot{x} + x + k_r(x - x_b) + k_{\text{rq}}(x - x_b)^2 + k_{\text{rc}}(x - x_b)^3 + 2\kappa(\dot{x} - \dot{x}_b) = 0 \quad (9a)$$

$$\ddot{x}_b + k_rm_r(x_b - x) - k_{\text{rq}}m_r(x_b - x)^2 + k_{\text{rc}}m_r(x_b - x)^3 + 2\kappa m_r(\dot{x}_b - \dot{x})$$

$$- \left(\sigma_0\tilde{z} + \sigma_1 v_r\left(1 - \frac{\sigma_0\text{sgn}(v_r)}{G(v_r)}\tilde{z}\right) + \sigma_2 v_r\right) \quad (9b)$$

$$\dot{\tilde{z}} = v_r\left(1 - \frac{\sigma_0\text{sgn}(v_r)}{G(v_r)}\tilde{z}\right) \quad (9c)$$

For ease of analysis of the current system, Eq. (9) can be rewritten compactly in the state space form as

$$\dot{x}_1 = x_2 \tag{10a}$$

$$\dot{x}_2 = -2\zeta x_2 - x_1 - k_r(x_1 - x_3) - k_{rq}(x_1 - x_3)^2$$
$$- k_{rc}(x_1 - x_3)^3 - 2\kappa(x_2 - x_4) \tag{10b}$$

$$\dot{x}_3 = x_4 \tag{10c}$$

$$\dot{x}_4 = -2\kappa m_r(x_4 - x_2) - k_r m_r(x_3 - x_1)$$
$$+ k_{rq}m_r(x_3 - x_1)^2 - k_{rc}m_r(x_3 - x_1)^3$$
$$- m_r\left(\sigma_0 x_5 + \sigma_1 v_r\left(1 - \frac{\sigma_0 x_5}{G(v_r)}\mathrm{sgn}(v_r)\right) + \sigma_2 v_r\right) \tag{10d}$$

$$\dot{x}_5 = v_r\left(1 - \frac{\sigma_0 x_5}{G(v_r)}\mathrm{sgn}(v_r)\right) \tag{10e}$$

with $[x_1, x_2, x_3, x_4, x_5] = [x(\tau), \dot{x}(\tau), x_b(\tau), \dot{x}_b(\tau), \tilde{z}(\tau)]$. Next, if v_{rv} represents the nondimensional constant reference velocity, v_r can be rewritten as $v_r = \dot{x}_b + v_{rv} = x_4 + v_{rv}$. For the analytical treatment of the current system, we follow the procedure outlined in Refs. [22,27] and, accordingly, modify Eq. (10) for the case of pure slipping motion $\mathrm{sgn}(v_r) = 1$ as

$$\dot{x}_1 = x_2 \tag{11a}$$

$$\dot{x}_2 = -k_{rc}x_1^3 - x_1^2 k_{rq} + 3x_1^2 k_{rc}x_3 - x_1 k_r - x_1 + 2x_1 k_{rq}x_3 - 3x_1 k_{rc}x_3^2$$
$$- 2x_2\kappa - 2x_2\zeta - k_{rq}x_3^2 + 2\kappa x_4 + k_r x_3 + k_{rc}x_3^3 \tag{11b}$$

$$\dot{x}_3 = x_4 \tag{11c}$$

$$\dot{x}_4 = k_{rc}m_r x_1^3 + x_1^2 k_{rq}m_r - 3x_1^2 k_{rc}m_r x_3 + x_1 k_r m_r$$
$$- 2x_1 k_{rq}m_r x_3 + 3x_1 k_{rc}m_r x_3^2$$
$$+ m_r\sigma_1\sigma_0 x_5 g_3 x_4^4 + x_4^3 m_r\sigma_{-1}v_{rv}\sigma_0 x_5 g_3 + x_4^3 m_r\sigma_1\sigma_0 x_5 g_2$$
$$+ x_4^2 m_r\sigma_1 v_{rv}\sigma_0 x_5 g_2$$
$$+ x_4^2 m_r\sigma_1\sigma_0 x_5 g_1 - 2x_4\kappa m_r + x_4 m_r\sigma_1\sigma_0 x_5 g_0$$
$$- x_4 m_r\sigma_2 + x_4 m_r\sigma_1 v_{rv}\sigma_0 x_5 g_1$$
$$+ m_r\sigma_1 v_{rv}\sigma_0 x_5 g_0 - m_r\sigma_2 v_{rv} + k_{rq}m_r x_3^2$$
$$+ 2\kappa m_r x_2 - m_r\sigma_1 v_{rv} - k_r m_r x_3 - k_{rc}m_r x_3^3$$
$$- m_r\sigma_0 x_5 - x_4 m_r\sigma_1 \tag{11d}$$

$$\dot{x}_5 = -\sigma_0 x_5 g_3 x_4^4 - x_4^3\sigma_0 x_5 g_2 - x_4^3 v_{rv}\sigma_0 x_5 g_3$$
$$- x_4^2 v_{rv}\sigma_0 x_5 g_2 - x_4^2\sigma_0 x_5 g_1 + x_4 - x_4 v_{rv}\sigma_0 x_5 g_1 \tag{11e}$$
$$- x_4\sigma_0 x_5 g_0 + v_{rv} - v_{rv}\sigma_0 x_5 g_0 . s$$

where g_i for $i = 0, 1, 2, 3$ are defined in Appendix A. Before proceeding further, we need to determine the fixed-points of Eq. (11), and are given by

$$x_{1s} = -\frac{g_0\sigma_2 v_{rv} + 1}{g_0}, x_{2s} = 0, x_{4s} = 0, x_{5s} = \frac{1}{\sigma_0 g_0} \tag{12}$$

whereas x_{3s} is governed by the roots of the following cubic equation

$$Ax_{3s}^3 + Bx_{3s}^2 + Cx_{3s} + D = 0 \tag{13}$$

where A, B, C, D are the function of system parameters and $v_{rv}, \neq 0$, and are defined as

$$A = k_{rc}g_0^3, \; B = 3k_{rc}\sigma_2 v_{rv}g_0^3 + 3k_{rc}g_0^2 - k_{rq}g_0^3,$$
$$C = 6k_{rc}g_0^2\sigma_2 v_{rv} - 2k_{rq}g_0^2 + 3k_{rc}g_0^3\sigma_2^2 v_{rv}^2$$
$$+ k_r g_0^3 + 3k_{rc}g_0 - 2k_{rq}g_0^3\sigma_2 v_{rv},$$
$$D = (\sigma_2 v_{rv}g_0 + 1)\big(k_{rc}g_0^2\sigma_2^2 v_{rv}^2 - k_{rq}g_0^2\sigma_2 v_{rv} + k_r g_0^2 \tag{14}$$
$$+ g_0^2 + 2k_{rc}\sigma_2 v_{rv}g_0 - k_{rq}g_0 + k_{rc}\big)$$

Therefore, depending on the coefficients of the cubic equation, we may have either only one set of fixed-points (one real with two complex conjugates roots of Eq. (13)) or three sets of fixed-points (three distinct real roots of Eq. (13)). For simplicity, we consider the scenario where Eq. (13) has only one real and two complex roots, or three repeated roots so that the analytical analysis will be carried out based on a set of unique real fixed-points. To ensure that Eq. (13) will have only one real root, the discriminant of polynomials should be less than zero. The discriminant for the cubic equation (Eq. (13)) is defined as

$$Ds = -27A^2D^2 + 18ABCD - 4AC^3 - 4B^3D + B^2C^2 \tag{15}$$

This solvability condition further puts the restriction on the ranges of k_{rq}, k_{rc} to get unique real fixed-points for the given value of k_r. Therefore, we have ensured that the numerical values of k_{rq} and k_{rc} are chosen such that we get unique real fixed-points of the system.

Next, a small parameter $\epsilon(\epsilon \ll 1)$ is introduced in Eq. (11) through following transformation

$$x_i(\tau) = x_{is} + \epsilon y_i(\tau), \; (\text{for } i = 1, 2, ..., 5) \tag{16}$$

where $y_i(\tau)$s are $\mathcal{O}(1)$ perturbations. Thus, Eq. (11) can be written as

$$\dot{y}_1 = y_2 \tag{17a}$$

$$\dot{y}_2 = -y_1 - k_r(y_1 - y_3) - 2\zeta y_2 - 2\kappa(y_2 - y_4) + h_1 h_2(y_1 - y_3)$$
$$+ 3h_1 k_{rq}(y_1 - y_3) - \epsilon(y_3^3 h_2 - 2y_3 y_1 h_2 + y_1^2 h_2)$$
$$- \epsilon^2 k_{rc}(y_1 - y_3)^3 \tag{17b}$$

$$\dot{y}_3 = y_4 \tag{17c}$$

$$\dot{y}_4 = \alpha y_4 h_4 + g_0 y_5\alpha\sigma_1 v_{rv}\sigma_0 + 2\kappa\alpha(y_2 - y_4)$$
$$+ y_1 k_r\alpha - y_3 k_r\alpha - y_5\alpha\sigma_0 + (3y_1\alpha h_1^2 - 3y_3\alpha h_1^2)k_{rc}$$
$$+ (-2y_1\alpha h_1 + 2y_3\alpha h_1)k_{rq} + \epsilon y_4^2(-\alpha\sigma_1\sigma_2 v_{rv}h_7 + h_6 h_7)$$
$$- 3k_{rc}(y_3 - y_1)^2\alpha h_1$$
$$+ k_{rq}(y_3 - y_1)^2\alpha + y_4 y_5\alpha\sigma_1\sigma_0 h_5$$
$$+ \epsilon^2\big(-y_4^3\alpha\sigma_1 h_0 h_8 - y_4^2 y_5\alpha\sigma_1\sigma_0 h_7 + k_{rc}\alpha(y_3 - y_1)^3\big) \tag{17d}$$

$$\dot{y}_5 = -v_{rv}g_0\sigma_0 y_5 - g_1 v_{rv}y_4 h_0$$
$$- \epsilon(g_0 y_5 y_4\sigma_0 + y_5 y_4 v_{rv}g_1\sigma_0 + y_4^2 v_{rv}g_2 h_0 + y_4^2 g_1 h_0)$$
$$- \epsilon^2(y_5 y_4^2\sigma_0 v_{rv}g_2 + y_4^3 v_{rv}g_3 h_0 + y_5 y_4^2\sigma_0 g_1 + y_4^3 g_2 h_0) \tag{17e}$$

where $h_0 = \frac{1}{g_0}, h_1 = h_0 + x_{s3} + \sigma_2 v_{rv}, h_2 = -3k_{rc}h_1 + k_{rq}, h_3 = h_1 - x_{s3} - \sigma_2 v_{rv}, h_4 = -\sigma_2 + \sigma_1 g_1 h_3 v_{rv},$

$h_5 = g_0 + v_{rv}g_1, h_6 = \alpha\sigma_1(h_1 - x_{s3}), h_7 = v_{rv}g_2 + g_1$, and $h_8 = g_2 + g_3v_{rv}$. Since nonlinearities in these equations appear as coefficients of higher orders of $\epsilon(> 0)$, the unperturbed system can be obtained by setting $\epsilon = 0$ in Eq. (17) for the linear stability analysis.

3 Linear Stability of Fixed-Points and Existence of Critical Points

The fixed-point's linear stability, along with the existence of Hopf bifurcation in the system, is investigated in this section. As mentioned earlier, The linearized system of equations can be obtained by setting $\epsilon = 0$ in Eq. (17) to get

$$\dot{y}_1 = y_2 \tag{18a}$$

$$\begin{aligned} \dot{y}_2 = &-y_1 - k_r(y_1 - y_3) - 2\zeta y_2 - 2\kappa(y_2 - y_4) + h_1h_2(y_1 - y_3) \\ &+ 3h_1k_{rq}(y_1 - y_3) \end{aligned} \tag{18b}$$

$$\dot{y}_3 = y_4 \tag{18c}$$

$$\begin{aligned} \dot{y}_4 = &m_r y_4 h_4 + g_0 y_5 m_r \sigma_1 v_{rv} \sigma_0 + 2\kappa m_r(y_2 - y_4) \\ &+ y_1 k_r m_r - y_3 k_r m_r - y_5 m_r \sigma_0 + 3y_1 m_r h_1^2 \\ &- 3y_3 m_r h_1^2 k_{rc} + (-2y_1 m_r h_1 + 2y_3 m_r h_1)k_{rq} \end{aligned} \tag{18d}$$

$$\dot{x}_5 = -v_{rv}g_0\sigma_0 y_5 - g_1 v_{rv} y_4 h_0 \tag{18e}$$

Accordingly, the characteristic equation for the system is obtained by substituting the synchronous solution for y_i (for $i = 1.5$) in the form of

$$\begin{pmatrix} y_1(\tau) \\ y_2(\tau) \\ y_3(\tau) \\ y_4(\tau) \\ y_5(\tau) \end{pmatrix} = \begin{pmatrix} y_{10} \\ y_{20} \\ y_{30} \\ y_{40} \\ y_{50} \end{pmatrix} e^{\lambda\tau} \tag{19}$$

into Eq. (18) and focusing on the nontrivial solutions for the system to get

$$\lambda^5 + f_1\lambda^4 + f_2\lambda^3 + f_3\lambda^2 + f_4\lambda + f_5 = 0 \tag{20}$$

where $f_i(i = 1, 2, \ldots, 5)$ are defined in Appendix-B and are functions of control gain parameters, the reference signal, and the primary system's characteristics. Note that the fixed-point's stability depends on the roots of the above characteristic equation for the given set of operational and system parameters. If all five roots of the above characteristic equation have a negative real part, the system is considered stable in a linear regime otherwise unstable. Since we can only vary the gain parameters and the reference signal for a given set of system parameters, the system's stability depends on these operational parameters. Therefore, there is a threshold/critical value for these operational parameters, which corresponds to a change in the system's stability. These threshold/critical points correspond to the Hopf bifurcation in the system and can be identified by setting $\lambda = i\omega$ with $\omega > 0$ in the- characteristic equation (Eq. (20)). This substitution leads to a set of two algebraic equations by equating real and imaginary parts to zero,

$$f_1\omega^4 - f_3\omega^2 + f_5 = 0 \tag{21}$$

$$\omega^5 - f_2\omega^3 + f_4\omega = 0 \tag{22}$$

For the current study, we select ζ (differential gain) and v_{rv} (velocity signal) as our operational parameters. Accordingly, we solve the

above simultaneous equations for ζ and v_{rv}. Due to the complexity involved in $f_i's$ ($i = 1, 2, 3, 4, 5$), we solve these two equations numerically to get the threshold/critical values of ζ and v_{rv}, i.e., $\zeta_{i,cr}$ and $v_{rv,cr}$. Furthermore, the solution of the linearized equations (Eq. (18)) at the critical point is given by

$$\mathbf{y}(\tau) = A_1\mathbf{r}_1 e^{i\omega\tau} + A_2\mathbf{r}_2 e^{-i\omega\tau} \tag{23}$$

In Eq. (23), $\mathbf{y}(\tau) = [y_1(\tau), y_2(\tau), y_3(\tau), y_4(\tau), y_5(\tau)]^T$ and $\mathbf{r}_1$ and $\mathbf{r}_2$ are the complex conjugate right eigenvectors of the characteristic matrix corresponding to eigenvalues $\lambda = i\omega$ and $\lambda = -i\omega$, respectively. Also, it should be noted that for $\mathbf{y}(\tau)$ to be a real-valued vector, A_1 and A_2 have to be complex conjugate constants. The right eigenvector $\mathbf{r}_1$ corresponding to $\lambda = i\omega$ is defined as

$$\mathbf{r}_1 = \begin{bmatrix} 1 \\ i\omega \\ \mathrm{Re}_1 + i m_1 \\ \mathrm{Re}_2 + i m_2 \\ \mathrm{Re}_3 + i m_3 \end{bmatrix} \tag{24}$$

Since the expressions for Re_m and Im_m ($m = 1, 2, 3$) are lengthy, and hence, not reported in the work for the sake of brevity. In the next step, we analyze the system using the perturbation method, more specifically, the method of multiple scales (MMS).

4 The Method of Multiple Scales

The linear stability analysis of our system in Sec. 3 determines the fixed-points' local stability for a given set of operational and system parameters. For a given set of parameters, if a small perturbation to a fixed-point dies out with time, then it is locally stable; however, if it increases with time, then it is globally unstable. The sensitivity of fixed-points toward initial perturbation in a locally stable point and its time evolution depends on the nature of the existing system's nonlinearity. If all perturbations die out with time, irrespective of their magnitude, then a locally stable point is considered as a globally stable point for the fixed-point. However, the small perturbation dies out, and the large perturbation settles down to a limit cycle close to the critical point in a locally stable point. A globally stable point is different from a locally stable point, which further leads to the existence of bistable regions. Since such a phenomenon relies on the system's nonlinearity, linear stability analysis is insufficient to analyze the bistable regime. Therefore, we perform a thorough nonlinear analysis of the system at Hopf points to establish the globally stable region of the fixed-points.

For the current analysis, we use a perturbation method, more specifically, the method of multiple scales, to determine the amplitudes and locations of limit cycles along with the nature of the Hopf bifurcation at the Hopf point. To begin, we first define different time scales as

$$T_0 = \tau, \ T_1 = \epsilon\tau, \ T_2 = \epsilon^2\tau, \ldots \tag{25}$$

Accordingly, the time-derivative operators also get modified to

$$\frac{\mathrm{d}}{\mathrm{d}\tau} = D_0 + \epsilon D_1 + \epsilon^2 D_2 + \mathcal{O}(\epsilon^3) \tag{26}$$

$$\frac{\mathrm{d}^2}{\mathrm{d}\tau^2} = D_{0,0} + 2\epsilon D_{0,1} + \epsilon^2(2D_{0,2} + D_{1,1}) + \mathcal{O}(\epsilon^3) \tag{27}$$

where $D_n = \frac{\partial}{\partial T_n}$ and $D_{m,n} = \frac{\partial^2}{\partial T_m \partial T_n}$. In the next step, we assume the solution for Eq. (17) as a series of ϵ till $\mathcal{O}(\epsilon^2)$ as

$$\begin{aligned} \mathbf{y}(\tau) &= \mathbf{y}_0(T_0, T_1, T_2) + \epsilon\mathbf{y}_1(T_0, T_1, T_2) + \epsilon^2\mathbf{y}_2(T_0, T_1, T_2) \\ &= \mathbf{y}_0 + \epsilon\mathbf{y}_1 + \epsilon^2\mathbf{y}_2 \end{aligned} \tag{28}$$

with

$$\mathbf{y}(\tau) = \begin{bmatrix} y_1(\tau) \\ y_2(\tau) \\ y_3(\tau) \\ y_4(\tau) \\ y_5(\tau) \end{bmatrix}, \quad \mathbf{y}_j(T_0, T_1, T_2) = \begin{bmatrix} y_{1,m}(T_0, T_1, T_2) \\ y_{2,m}(T_0, T_1, T_2) \\ y_{3,m}(T_0, T_1, T_2) \\ y_{4,m}(T_0, T_1, T_2) \\ y_{5,m}(T_0, T_1, T_2) \end{bmatrix} j = 0, 1, 2 \tag{29}$$

Next, we select the nondimensional reference velocity v_{rv} as our bifurcation parameter, and perturb v_{rv} as

$$v_{rv} = v_{rv,cr} + \epsilon^2 k_1 \tag{30}$$

where $v_{rv,cr}$ is the value of v_{rv} at the Hpof/critical point with $\zeta = \zeta_{cr}$. k_1 is $\mathcal{O}(1)$ quantity and is chosen such that perturbed v_{rv} remains in the unstable region. Also, due to the perturbation in v_{rv}, the terms depending on v_{rv} will get perturbed as well in the form of $h_i(v_{rv}) = h_i(v_{rv,cr}) + \epsilon^2 \left(\frac{dh_i}{dv_{rv}}_{v_{rv}=v_{rv,cr}} \right) k_1 + \mathcal{O}(\epsilon^4) \approx h_{i,cr} + \epsilon^2 h_{i,p} k_1$. Next, we substitute Eqs. (26)–(30) in Eq. (17), expand in Taylor series for smaller values of ϵ, and equate the coefficients of different orders of ϵ to zero to get $\mathcal{O}(\epsilon^0)$

$$D_0 x_{1,1} - x_{2,1} = 0 \tag{31a}$$

$$D_0 x_{2,1} + 2(x_{2,1} - x_{4,1})\kappa - (x_{3,1} - x_{1,1})k_r + h_{1,cr}(x_{3,1} - x_{1,1})k_{rq} + x_{1,1} + (x_{3,1} - x_{1,1})h_{1,cr}h_{2,cr} + 2\zeta x_{2,1} = 0 \tag{31b}$$

$$D_0 x_{3,1} - x_{4,1} = 0 \tag{31c}$$

$$D_0 x_{4,1} - 2m_r(x_{2,1} - x_{4,1})\kappa + m_r(x_{3,1} - x_{1,1})k_r - 2m_r h_{1,cr}(x_{3,1} - x_{1,1})k_{rq}$$
$$+ m_r \sigma_0 x_{5,1} - m_r \sigma_1 \sigma_0 x_{5,1} v_{rv,cr}^3 g_{2,cr} + m_r \sigma_1 \sigma_0 x_{5,1} v_{rv,cr} h_{5,cr} - 3m_r k_{rc} x_{1,1} h_{1,cr}^2 + 3m_r k_{rc} x_{3,1} h_{1,cr}^2 \tag{31d}$$
$$+ m_r x_{4,1} h_{4,cr} + m_r \sigma_1 \sigma_0 x_{5,1} v_{rv,cr}^2 h_{7,cr} = 0$$

$$D_0 x_{5,1} + x_{4,1} v_{rv,cr} g_{1,cr} h_{0,cr} + \sigma_0 x_{5,1} v_{rv,cr} g_{0,cr} = 0 \tag{31e}$$

$\mathcal{O}(\epsilon^1)$

$$D_0 x_{1,2} - x_{2,2} = -D_1 x_{1,1} \tag{32a}$$

&- x_{4,1}k_1 g_{1,cr}h_{0,cr} - x_{4,1}v_{rv,cr}g_{1,cr}k_1 h_{0,p}
\end{aligned}
\tag{33e}
$$

Since the equations corresponding to $\mathcal{O}(\epsilon^0)$ (Eq. (31)) are similar to the linearized equations, i.e., Eq. (18) with critical/Hopf control parameters, the solution for Eq. (31) can be written in the form of the generalized right-eigen vector as

$$
\mathbf{y}_{0(T_0,T_1,T_2)} = A_1(T_1,T_2)\mathbf{r}_1 e^{i\omega T_0} + A_2(T_1,T_2)\mathbf{r}_2 e^{-i\omega T_0}
\tag{34}
$$

In the above-assumed solution form, A_1 and A_2 are complex and conjugate functions. To get the closed form solution for $A_1(T_1,T_2)$ and $A_2(T_1,T_2)$, we proceed to the higher order of ϵ. Substitution of Eq. (34) in $\mathcal{O}(\epsilon^1)$ equations, i.e., Eq. (32) leads to the appearance of $e^{2i\omega T_0}, e^{-2i\omega T_0}, e^{i\omega T_0}$, and $e^{-i\omega T_0}$ in the resultant equations. However, the appearance of secular terms $e^{i\omega T_0}$ and $e^{-i\omega T_0}$ give rise to linear growth in the solution for $\mathbf{y}_1$, and have to be eliminated from the corresponding equations to get a bounded solution for $\mathbf{y}_1$. In particular, this step requires that the dot product of the vector consisting of the coefficients of $e^{i\omega T_0}$ $(e^{-i\omega T_0})$ with the generalized left eigenvectors corresponding to $\lambda = i\omega (\lambda = -i\omega)$ should be zero [31]. The generalized left eigenvectors $\mathbf{l}_1$ for the characteristic matrix corresponding to $e^{i\omega T_0}$ is

$$
\mathbf{l}_1 = [1\, Lre_1 + iLim_1\ Lre_2 + iLim_2\ Lre_3 + iLim_3\ Lre_4 + iLim_4.]
\tag{35}
$$

Since the expressions for the components of left eigenvectors are lengthy and involved, these are not reported here for the sake of brevity. Furthermore, the left-eigen vector $\mathbf{l}_2$ for the eigenvalue $\lambda = -i\omega$ is the complex conjugate of $\mathbf{l}_1$, and hence, not reported in paper. The coefficient vectors $\mathbf{u}_1$ and $\mathbf{u}_2$ corresponding to $e^{i\omega T_0}$ and $e^{-i\omega T_0}$, respectively are

$$
\mathbf{u}_1 = \frac{\partial A_1(T_1,T_2)}{\partial T_1}
\begin{bmatrix}
1 \\
i\omega \\
Re_1 + iI_1 \\
Re_2 + im_2 \\
Re_3 + im_3
\end{bmatrix}, \quad
\mathbf{u}_2 = \frac{\partial A_2(T_1,T_2)}{\partial T_1}
\begin{bmatrix}
1 \\
-i\omega \\
Re_1 - im_1 \\
Re_2 - im_2 \\
Re_3 - im_3
\end{bmatrix}
\tag{36}
$$

It can be easily observed that $\mathbf{u}_1$ and $\mathbf{u}_2$ are complex conjugates of each other and have the same coefficients as the generalized right eigenvector. This observation can be further justified by the appearance of only quadratic nonlinear terms in $\mathcal{O}(\epsilon^1)$ equations. These quadratic nonlinear terms further give rise to either

$e^{i\omega T_0}(e^{-i\omega T_0})$ or constant terms, and hence, do not contribute to secular terms. As discussed above, to remove secular terms corresponding to $e^{i\omega T_0}$ at $\mathcal{O}(\epsilon^1)$ we use the solvability condition $\mathbf{l}_1 \cdot \mathbf{u}_1 = 0$, which further implies

$$
\begin{aligned}
\frac{\partial A_1(T_1,T_2)}{\partial T_1}[&1 - \omega Lim_1 + Lre_2 Re_1 - Lim_2\, Im_1 \\
&+ Lre_3 Re_2 - Lim_3 Im_2 + Lre_4 Re_3 - Lim_4 Im_3] \\
&+ i(\omega Lre_1 + Lre_2 Im_1 + Lim_2 Re_1 + Lre_3 Im_2 \\
&+ Lim_3 Re_2 + Lre_4 Im_3 + Lim_4 Re_3)] = 0
\end{aligned}
\tag{37}
$$

$$
\implies \frac{\partial A_1(T_1,T_2)}{\partial T_1} = 0.
\tag{38}
$$

Equation (38) follows from Eq. (37) as the term inside the bracket in Eq. (37) will not be zero for the given values of parameters at the Hopf point. Furthermore, the removal of secular terms corresponding to $e^{-i\omega T_0}$ using the solubility condition also leads to

$$
\implies \frac{\partial A_2(T_1,T_2)}{\partial T_1} = 0
\tag{39}
$$

However, these results (Eqs. (38) and (39)) suggest that A_1 and A_2 do not depend on T_1 and are only the functions of T_2. Furthermore, to obtain the nonzero solutions of A_1 and A_2, we proceed to the next order of ϵ, i.e., equations corresponding to $\mathcal{O}(\epsilon^2)$, for which the solution at the $\mathcal{O}(\epsilon^1)$, i.e., $\mathbf{y}_1$ is needed (as evident from Eq. (33)). To get the solution for $\mathbf{y}_1$, we substitute $\frac{\partial A_1}{\partial T_1} = 0$ and $\frac{\partial A_2}{\partial T_1} = 0$, along with the assumed form of solution for $\mathbf{y}_0$ (Eq. (34)) in Eq. (32), and use the Harmonic balance method. For this, we assume the following form of the solution for $\mathbf{y}_1$

$$
\begin{aligned}
\mathbf{y}_1(T_0,T_1,T_2) = &A_1^2(T_2)\mathbf{B}_{11}e^{2i\omega T_0} + A_2^2(T_2)\mathbf{B}_{22}e^{-2i\omega T_0} \\
&+ A_1(T_2)A_2(T_2)\mathbf{B}_{12},
\end{aligned}
\tag{40}
$$

where coefficient vector $\mathbf{B}_{11}, \mathbf{B}_{22}$ and $\mathbf{B}_{12}$ are defined as

$$
\mathbf{B}_{11} = \begin{bmatrix} b_{11} \\ b_{12} \\ b_{13} \\ b_{14} \\ b_{15} \end{bmatrix}, \mathbf{B}_{22} = \begin{bmatrix} b_{21} \\ b_{22} \\ b_{23} \\ b_{24} \\ b_{25} \end{bmatrix}, \text{ and } \mathbf{B}_{12} = \begin{bmatrix} b_{31} \\ b_{32} \\ b_{33} \\ b_{34} \\ b_{35} \end{bmatrix}
\tag{41}
$$

We are substituting Eq. (40) in Eq. (32) and collecting $e^{2i\omega T_0}$, $e^{-2i\omega T_0}$ and constant terms, we get 15 simultaneous algebraic equations in terms of b_{mn} (for $m = 1, 2, 3$ and $n = 1.5$). Since the closed-form expressions for b_{mn} are lengthy, we do not report these expressions for brevity. We substitute $\mathbf{y}_0$ and $\mathbf{y}_1$ in terms of $A_1(T_2)$ and $A_2(T_2)$ in $\mathcal{O}(\epsilon^2)$ equations (Eq. (33)) and collecting the coefficients of secular terms, i.e., $e^{i\omega T_0}$ and $e^{-i\omega T_0}$. If $\mathbf{V}_1$ and $\mathbf{V}_2$ are the secular coefficient vectors corresponding to $e^{i\omega T_0}$ and $e^{-i\omega T_0}$, respectively, then secular terms from Eq. (33) can be removed by $\mathbf{l}_1 \cdot \mathbf{V}_1 = 0$ and $\mathbf{l}_2 \cdot \mathbf{V}_2 = 0$. These solvability conditions lead to two first-order complex conjugate differential equations governing the slow time evolution of A_1 and A_2. Therefore, we switch to polar coordinates by substituting

$$A_1(T_2) = \frac{R(T_2)e^{i\phi(T_1)}}{2}, \text{ and } A_2(T_2) = \frac{R(T_2)e^{-i\phi(T_1)}}{2} \quad (42)$$

into the complex differential equation resulting from $\mathbf{l}_1 \cdot \mathbf{V}_1 = 0$. We separate the resultant equation into real and imaginary parts and solve for $\partial R(T_2)/\partial T_2$ and $\partial \phi(T_2)/\partial T_2$ as

$$\frac{\partial R(T_2)}{\partial T_2} = p_{11}k_1 R + p_{12}R^3 \quad (43)$$

$$\frac{\partial \phi(T_2)}{\partial T_2} = p_{21}k_1 + p_{22}R^2 \quad (44)$$

where $p_{11}, p_{12}, p_{21},$ and p_{22} are functions of system parameters, $\zeta_{cr}, v_{rv,cr},$ and ω. As $p_{11}, p_{12}, p_{21},$ and p_{22} are very long expressions of the above-mentioned parameters, we do not report these in the current work for brevity. The equations governing the R and ϕ in the original time scale (τ) can be expressed using Eq. (26) as

Table 1 Numerical values of system's parameters [32]

$m_t(\text{kg})$	1.5	k_p	$2e^4$
$m_b(\text{N} - \text{s/m})$	0.75	$X_0(\text{m})$	0.0007353

f_c	0.35	a	2.5

$$\frac{dR}{d\tau} = \epsilon\frac{\partial R}{\partial T_1} + \epsilon^2\frac{\partial R}{\partial T_2} = \epsilon^2\left(p_{11}k_1 R + p_{12}R^3\right) \quad (45a)$$

$$\frac{\partial \phi}{\partial \tau} = \epsilon\frac{\partial \phi}{\partial T_1} + \epsilon^2\frac{\partial \phi}{\partial T_2} = \epsilon^2\left(p_{21}k_1 + p_{22}R^2\right) \quad (45b)$$

Further, $x_i(\tau)$ can be obtained by utilizing Eqs. (16), (28), (34), (42), and (45).

5 Results and Discussions

In this section, we examine the analytical results presented in Secs. 3 and 4 through numerical simulations. For our numerical simulation, we use the parameter values listed in Table 1. We first analyze the linear stability of the system in the parametric space of ζ and v_{rv} followed by the validation of our analytical formulation. Later on, by utilizing our analytical findings, we present the different regions of sub and supercritical Hopf bifurcation on linear stability boundaries. Finally, a detailed bifurcation analysis is presented.

5.1 Linear Stability Curves. In this section, we present the effect of the nonlinear components of friction isolator on the linear stability of the system. For this step, we plot the stability curves for different combinations of k_{rq} and k_{rc} on the operational parameter region of $\zeta - v_{rv}$ and are shown in Figs. 2–4. For ease of understanding, the unstable and stable regions are denoted by "U" and "S," respectively.

As mentioned earlier, it is mathematically challenging to get analytical expressions for $v_{rv,cr}$ and ζ_{cr}, hence, we obtain stability boundaries numerically by solving Eqs. (21) and (22) along with Eq. (13) for the varying values of frequency ω in a range $\omega \in (\omega_1, \omega_2)$. Since ω_1 and ω_2 are functions of system parameters, their numerical values vary from one case to another. On solving Eqs. (21) and (22) along with Eq. (13), for a given range of frequency, we get negative values of ζ and vrv. However, as negative values of the control gain and the reference signal are not feasible, we plot the stability curves for the positive values of parameters.

From Figs. 2–4, we can easily observe that, compared to the case of linear FI, the inclusion of quadratic and cubic nonlinearities in the FI increases the fixed-point's stability significantly. This observation further implies that the nonlinearities in FI support a wider range of stable operating conditions. However, the relative effects of quadratic/cubic nonlinearity on the stability region for a given value

Fig. 2 Comparison of stability region (a) for different values of cubic nonlinearity and $k_{rq} = 0.2$, and (b) for different values of quadratic nonlinearity and $k_{rc} = 0.2$ in nonlinear FI with linear FI. Other parameters are $\sigma_0 = 110$, $\sigma_1 = 1.37$, $\sigma_2 = 0.0823$, $f_s = 0.44$, $f_c = 0.35$, $\kappa = 0.001$, $a = 2.5$, $k_r = 0.5$, $k_{rq} = 0.2$ and $m_r = 2$.

of cubic/quadratic nonlinearity in various scenarios are different. For example, Fig. 2 shows the stability boundaries for different values of cubic/quadratic nonlinearity for a given nonzero value of quadratic/cubic and linear stiffness whereas Fig. 3 shows the stability boundaries with different values of cubic/quadratic nonlinearity in the absence of quadratic/cubic nonlinearities and nonzero linear stiffness, and Fig. 4 shows stability boundaries for different values of cubic/quadratic nonlinearity in the absence of quadratic/cubic and linear stiffness. From Figs. 2 and 3, it can be observed that the relative effects of cubic and quadratic non-linearities on the fixed-point's stability are almost identical with or without the other component of nonlinearity. This further implies that the rate of increase in stability with the increase in cubic nonlinearity is approximately the same as with the increase in quadratic nonlinearity. However, we emphasize that the overall stability at the given value of cubic nonlinearity (Fig. 3(a)) is higher than that at quadratic nonlinearity (Fig. 3(b)). Furthermore, from Fig. 4, it can be observed that although the rate of increase in stability with quadratic nonlinearity (Fig. 4(b)) is much higher than cubic

nonlinearity, the overall stability boundary for a given value of cubic nonlinearity is significantly larger than the case of quadratic nonlinearity. These observations further suggest that increasing the cubic stiffness of FI is more beneficial than increasing the quadratic stiffness. Having established the effect of nonlinear stiffness on the fixed-point's stability, we analyze the Hopf bifurcation on the stability curves using analytical results obtained by MMS. However, before this step, we must validate our analytical results, which can be done by comparing them with numerical simulations and presented next.

5.2 Validation of Method of Multiple Scales. To evaluate the accuracy of the MMS, we compare the solution of the system obtained from the slow-flow equations to the one obtained from Eq. (11) using the MATLAB ODE solver "ode45." We first present the time response of the motion stage with nonlinear FI for two sets of operational parameters close to the Hopf point. In particular, we respectively choose two nondimensional reference velocities with a smaller and a larger value, i.e., $v_{rv} = 0.0495 < v_{rv,cr} = 0.05$,
Fig. 3 Comparison of stability region (a) in the absence of quadratic stiffness ($k_{rq}=0$) for different values of cubic nonlinearity (b) in the absence of cubic stiffness ($k_{rc}=0$) for different values of cubic nonlinearity in nonlinear FI with linear FI. Other parameters are $\sigma_0=110$, $\sigma_1=1.37$, $\sigma_2=0.0823$, $f_s=0.44$, $f_c=0.35$, $\kappa=0.001$, $a=2.5$, $k_r=0.5$, and $m_r=2$.
Fig. 4 Comparison of stability region (a) in the absence of cubic and linear stiffness ($k_{rc}=k_r=0$) for different values of quadratic nonlinearity and (b) in the absence of quadratic and linear stiffness $k_{rq}=k_r=0$) for different values of cubic nonlinearity in nonlinear FI with linear FI. Other parameters are $\sigma_0=110$, $\sigma_1=1.37$, $\sigma_2=0.0823$, $f_s=0.44$, $f_c=0.35$, $\kappa=0.001$, $a=2.5$, and $m_r=2$.

$\zeta_{cr} = 0.11873$, and $v_{rv} = 0.09 < v_{rv,cr} = 0.1$, $\zeta_{cr} = 0.09502$. Since both sets of parameters are in the unstable regime, we obtain a gradually increasing periodic response of different amplitudes as shown in Fig. 5. We emphasize that these time responses are shifted to the origin set at the fixed-point (Eq. (12)). From Fig. 5, it can be easily observed that the analytical solution of the system from MMS exhibits an excellent match with the numerical solution of the system. We repeat the same steps for the motion stage with linear FI and two sets of operational parameters, viz., $v_{rv} = 0.0495 < v_{rv,cr} = 0.05$, $\zeta_{cr} = 0.24562$ and $v_{rv} = 0.09 < v_{rv,cr} = 0.1$, $\zeta_{cr} = 0.19082117$. The results are shown in Fig. 6 and we observe a good match between the two approaches for the motion stage with linear FI. Hence, our analytical solutions (Eq. (45)) are valid.

5.3 Hopf Bifurcation. In this section, we analyze the different regions of super and subcritical Hopf bifurcation on the stability lobes. When the system changes its stability through the Hopf

bifurcation, the fixed-points settle down to a limit cycle close to Hopf point. Furthermore, the location of a limit cycle with respect to the Hopf point decides the nature of Hopf bifurcation. More specifically, in the case of supercritical Hopf bifurcation, these limit cycles exist in the unstable region only, whereas the existence of limit cycles close to the Hopf point in the stable regime signifies subcritical Hopf bifurcation. We emphasize that the presence of supercritical Hopf bifurcation leads to the fixed-point's global stability of the stable region, whereas subcritical bifurcation leads to a bistable region in the system. Therefore, it is an essential step toward the understanding of the criticality of Hopf bifurcation on the stable curves.

From Figs. 2–4, we can observe that the location of an unstable region with respect to a Hopf point is not uniform in case of perturbation in $v_{rv,cr}$, i.e., the unstable v_{rv} is higher for $v_{rv,cr}$ of low values and lower for $v_{rv,cr}$ of high values. This further implies that the sign of k_1 in Eq. (30) will vary, i.e., positive for low values of $v_{rv,cr}$

Fig. 5 Comparison of analytical and numerical simulation for (a) ζ_{cr}=0.11873, v_{rv}=0.0495<$v_{rv,cr}$= 0.05, (b) ζ_{cr}=0.09502, v_{rv}=0.09<$v_{rv,cr}$=0.1, PD controlled motion stage with nonlinear friction isolator. Other parameters are σ_0=110, σ_1=1.37, σ_2=0.0823, f_s=0.44, f_c=0.35, κ=0.001, a=2.5, m_r=2, k_{rq}=0.2, k_{rc}=0.2, and k_r=0.5.

Fig. 6 Comparison of analytical and numerical simulation for (a) ζ_{cr}=0.24562, v_{rv}=0.0495<$v_{rv,cr}$=0.05, (b) ζ_{cr}=0.19082117, v_{rv}=0.09<$v_{rv,cr}$=0.1, PD controlled motion stage with linear friction isolator. Other parameters are σ_0=110, σ_1=1.37, σ_2=0.0823, f_s=0.44, f_c=0.35, κ=0.001, a=2.5, m_r=2, and k_r=0.5.

and negative for high values of $v_{rv,cr}$. However, in the case of perturbation in ζ_{cr}, the unstable region always lies on the left of the Hopf point, which further leads to a consistent sign (-ve) for k_1. Therefore, for the sake of simplicity in determining the transition points from super to subcritical Hopf bifurcation or vice versa, we perturb ζ as $\zeta = \zeta_{cr} - \epsilon^2 k_1$, and follow the procedure mentioned in Sec. 4 to get

$$\frac{dR}{d\tau} = \epsilon^2 \left(q_{11} k_1 R + q_{12} R^3 \right) \tag{46a}$$

$$\frac{\partial \phi}{\partial \tau} = \epsilon^2 \left(q_{21} k_1 + q_{22} R^2 \right) \tag{46b}$$

where q_{11}, q_{12}, q_{21}, and q_{22} depend on the system characteristics, critical operational parameters, and ω. Furthermore, the amplitude of the periodic solutions near the Hopf points can be estimated by setting $\dot{R} = 0$ in Eq. (46a), i.e., the nontrivial solution of Eq. (46a) and is given by

$$R = \sqrt{\frac{-q_{11} k_1}{q_{12}}} \tag{47}$$

Equation (47) plays an essential role in determining the criticality of Hopf bifurcation. In Eq. (47), if $\frac{q_{11}}{q_{12}}$ is negative then for R to be a real quantity k_1 should be positive. This further implies that limit cycles will exist in a linearly unstable region only, and the Hopf bifurcation will be supercritical. However, if for another set of critical parameter values $\frac{q_{11}}{q_{12}}$ get positive then for a real value of R, k_1 should be negative. Hence, limit cycles exist in the linear stable region, and the Hopf-bifurcation will be subcritical. After determining the criteria for subcritical and supercritical Hopf bifurcations, we evaluate $\frac{q_{11}}{q_{12}}$ at every Hopf point on the stability curve and decide the characteristic of Hopf bifurcation. Figures 7(a) and 7(b) show the characteristic of Hopf bifurcation on the stability boundary for the MBMS with nonlinear and linear FI, respectively. From both figures, we can observe that supercritical Hopf bifurcations occur at low values of v_{rv}. At the same time, fixed-points lose stability through subcritical Hopf bifurcations for high values of v_{rv}.

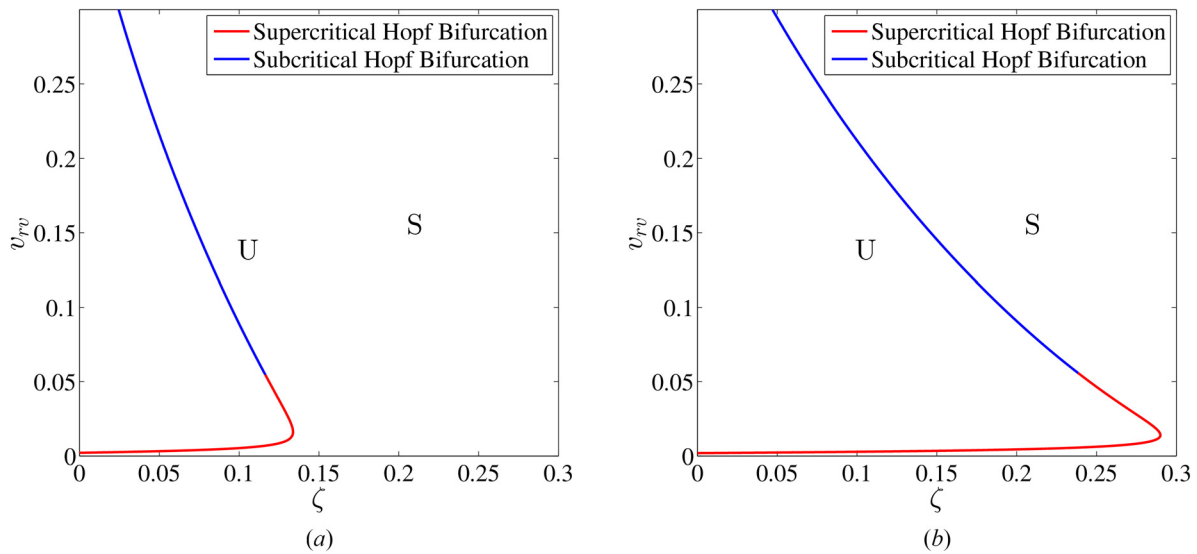

Fig. 7 Criticality of Hopf bifurcation in the motion stage with (a) with nonlinear FI $\left(k_{rc}=0.2, k_{rq}=0.2 \right)$ and (b) linear FI $\left(k_{rc}=k_{rq}=0 \right)$. Other parameters are $\sigma_0=110, \sigma_1=1.37, \sigma_2=0.0823, f_s=0.44, f_c=0.35, \kappa=0.001, a=2.5, m_r=2,$ and $k_r=0.5$.

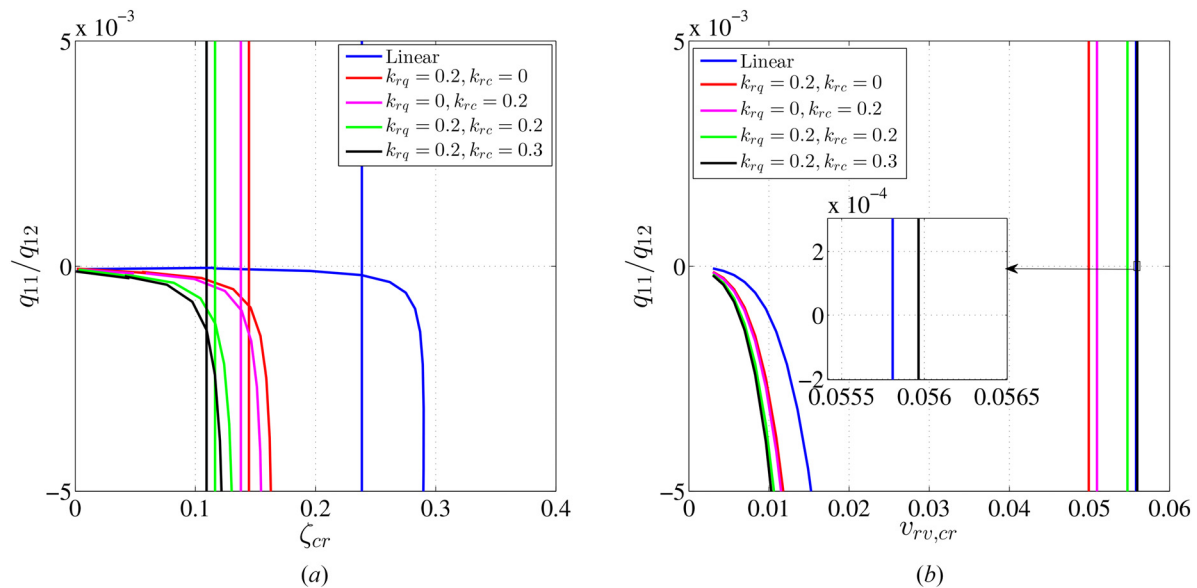

Fig. 8 Variation of q_{11}/q_{12} with (a) ζ_{cr} and (b) $v_{rv,cr}$ for different values of k_{rq} and k_{rc}. Other parameters are $\sigma_0=110, \sigma_1=1.37, \sigma_2=0.0823, f_s=0.44, f_c=0.35, \kappa=0.001, a=2.5, m_r=2,$ and $k_r=0.5$.

At first glance on Figs. 7(a) and 7(b), it appears that there is no effect of nonlinearity of FI on the subcritical and supercritical Hopf bifurcation regions on the stability curve, and transition point remains the same with nonlinear and linear FI. Therefore, to demonstrate the effect of nonlinear parameters of FI (k_{rq}, k_{rc}) on the criticality of Hopf bifurcation, we plot $\frac{q_{11}}{q_{12}}$ with different values of ζ_{cr} and $v_{rv,cr}$ for different sets of k_{rq} and k_{rc}, and the results are shown in Figs. 8(a) and 8(b), respectively.

From Fig. 8(a), it can be noted that the inclusion of nonlinearity in FI reduces the range of ζ_{cr} corresponding to supercritical Hopf bifurcation. However, this can be further justified by the fact that the nonlinearity shrinks the unstable region by decreasing ζ_{cr} values which lead to a decrease in the effective range of ζ_{cr} for supercritical Hopf bifurcation. Instead, Figs. 8(a) and 8(b) provide more information about the effect of k_{rq} and k_{rc} on the criticality of Hopf bifurcation. From Figs. 8(a) and 8(b), we can easily observe that the inclusion of nonlinearity in FI can decrease or increase the region of supercritical Hopf bifurcation depending on the numerical values of k_{rq} and k_{rc}. The optimization of these values for a larger

region of supercritical Hopf bifurcation and globally stable region is left for future work.

We emphasize that these analytical findings only provide the amplitude of limit cycles close to the Hopf point and characteristics of Hopf bifurcation on the stability boundaries. Therefore, to observe the global behavior of the system in the unstable region, we employ the numerical bifurcation analysis and present in the Sec. 5.4. Note that this step not only provides information about the large amplitude response of the system but also further verifies our analytical findings.

5.4 Bifurcation Analysis. To perform the numerical bifurcation analysis for the motion stage with nonlinear and linear FI, we solve the system of ODEs given by Eq. (10) using MATLAB ODE solver "ode45." The bifurcation plots, showing the extreme points of x_1, i. e., the error amplitude of the motion stage (corresponding to $x_2 = 0$), for the motion stage with nonlinear and linear FI have been shown in Figs. 9 and 10, respectively. The numerical bifurcation analysis can

Fig. 9 Numerical bifurcation diagram of motion stage with nonlinear FI with v_{rv} as bifurcation parameter for (a) $\zeta=0.06$ and (b) $\zeta=0.1$. Other parameters are $\sigma_0=110, \sigma_1=1.37, \sigma_2=0.0823, f_s=0.44, f_c=0.35, \kappa=0.001, a=2.5, m_r=2, k_{rq}=0.2, k_{rc}=0.2,$ and $k_r=0.5$.

Fig. 10 Numerical bifurcation diagram of motion stage with linear FI with v_{rv} as bifurcation parameter for (a) $\zeta=0.06$ and (b) $\zeta=0.1$. Other parameters are $\sigma_0=110, \sigma_1=1.37, \sigma_2=0.0823, f_s=0.44, f_c=0.35, \kappa=0.001, a=2.5, m_r=2,$ and $k_r=0.5$.

be performed by making either of the operational parameters a constant and varying the another. However, to show the existence of super- and subcritical Hopf bifurcations for lower and higher values of v_{rv}, respectively, as observed in Sec. 5.3, we have fixed ζ and varied v_{rv}. To plot these numerical bifurcation diagrams, we vary v_{rv} in upward and downward directions so that the system loses and gains stability through Hopf bifurcation. For completeness, we have also plotted these numerical bifurcation diagrams for two different values of ζ. To get a better picture of the dynamics of the motion stage with nonlinear and linear FI, the bifurcation diagrams close to the Hopf points are shown in the inset of Figs. 9 and 10. From these numerical bifurcation diagrams, we can easily observe the existence of stable limit cycles with fixed-point solutions at higher values of v_{rv} for a given value of ζ, which implies Hopf bifurcation is subcritical by nature. However, for lower values of v_{rv}, stable limit cycles exist in the unstable region only, which indicates supercritical bifurcation. Both of these observations are consistent with our analytical findings in Sec. 5.3. Furthermore, in the case of the motion stage with nonlinear

FI, the response amplitude for higher values of v_{rv} is relatively smaller than the ones corresponding to the motion stage with linear FI. For a better understanding of the dynamics of a PD-controlled motion stage with nonlinear and linear FI, the zoomed views of Figs. 9 and 10 have been shown in Figs. 11 and 12, respectively. For the sake of brevity, we only present these zoomed views for

differential gains of higher values, i.e., $\zeta = 0.1$. The corresponding representative phase portraits for different values of v_{rv} have been shown inside these zoomed figures. From Figs. 11 and 12, we can easily observe that in both cases, close to Hopf points, stable period-1 solutions lose stability through period-doubling bifurcation. This further leads to the appearance of period-2 solutions, which can also be observed from the phase portraits (Figs. 11(a) and 11(d) and 12(a) and 12(d)). Furthermore, in the case of nonlinear FI, the system exhibits only period-4 solutions away from the Hopf points, and there is no exchange in the stability of limit cycles away from the Hopf points (Figs. 11(b) and 11(c)). However, in the case of linear FI, apart from the coexistence of period-1 and period-2 solutions (as can be seen by phase portraits for $v_{rv} = 0.02$ in Fig. 12(a)), there is a continuous exchange of stability between period-1 and period-2 solutions as shown in Figs. 12(a)–12(d). Also, when comparing Figs. 11 and 12 in terms of subplots (i) and (ii), we observe that the branch of stable period1 solutions close to Hopf point is significantly smaller in case of linear FI when compared to the case of nonlinear FI. This observation further signifies the importance of nonlinear FI over linear FI.

We perform the quantitative match between MMS results and numerical simulations for completeness. For this step, we use the fixed-arc-length continuation scheme [33] to get the branch of limit cycles close to the Hopf point and later compare it with the branch of limit cycles obtained using the slow-flow equation emerging from

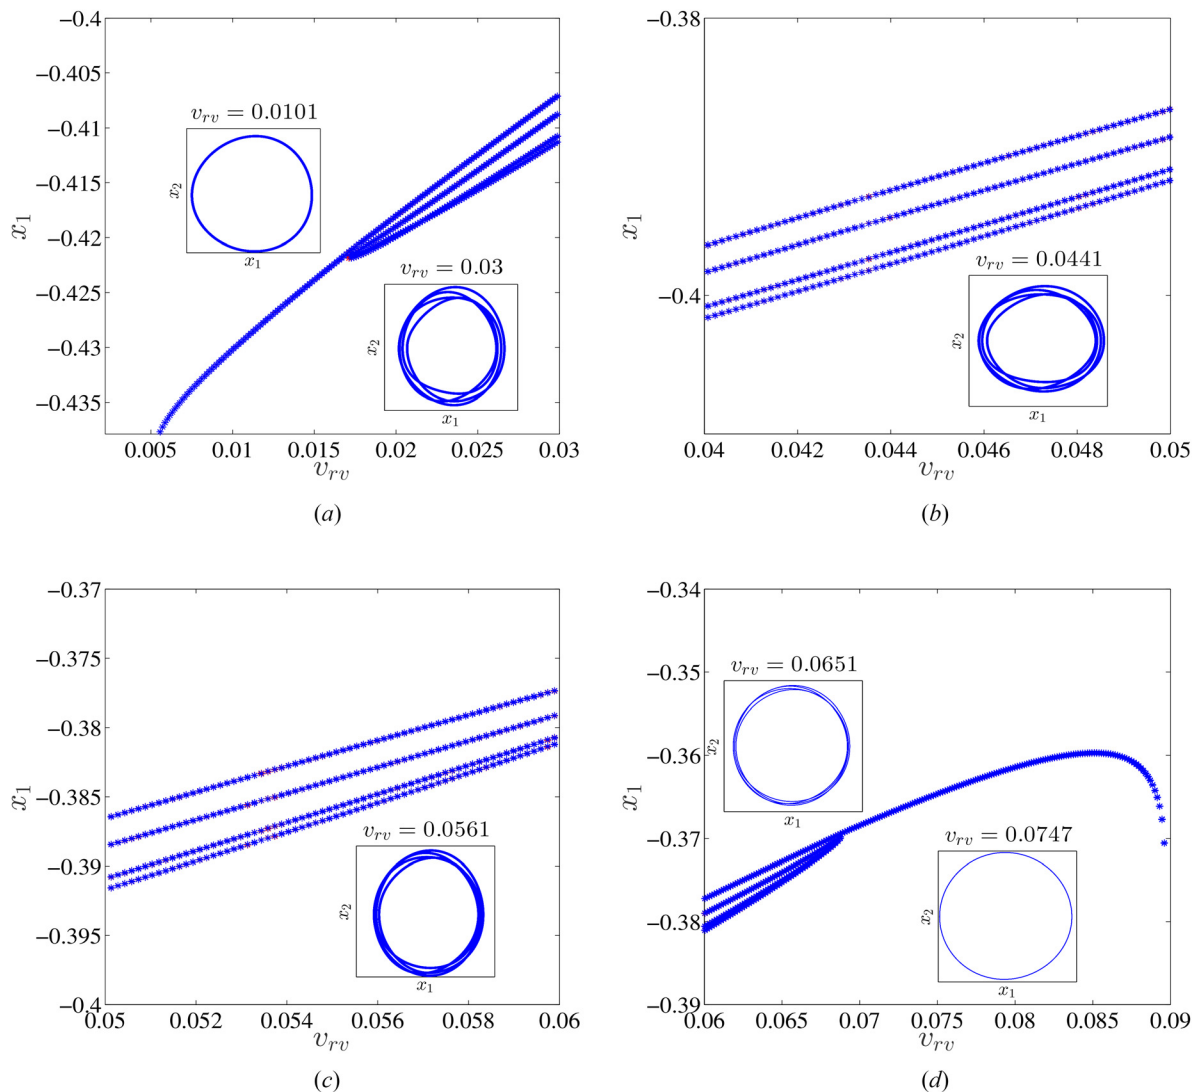

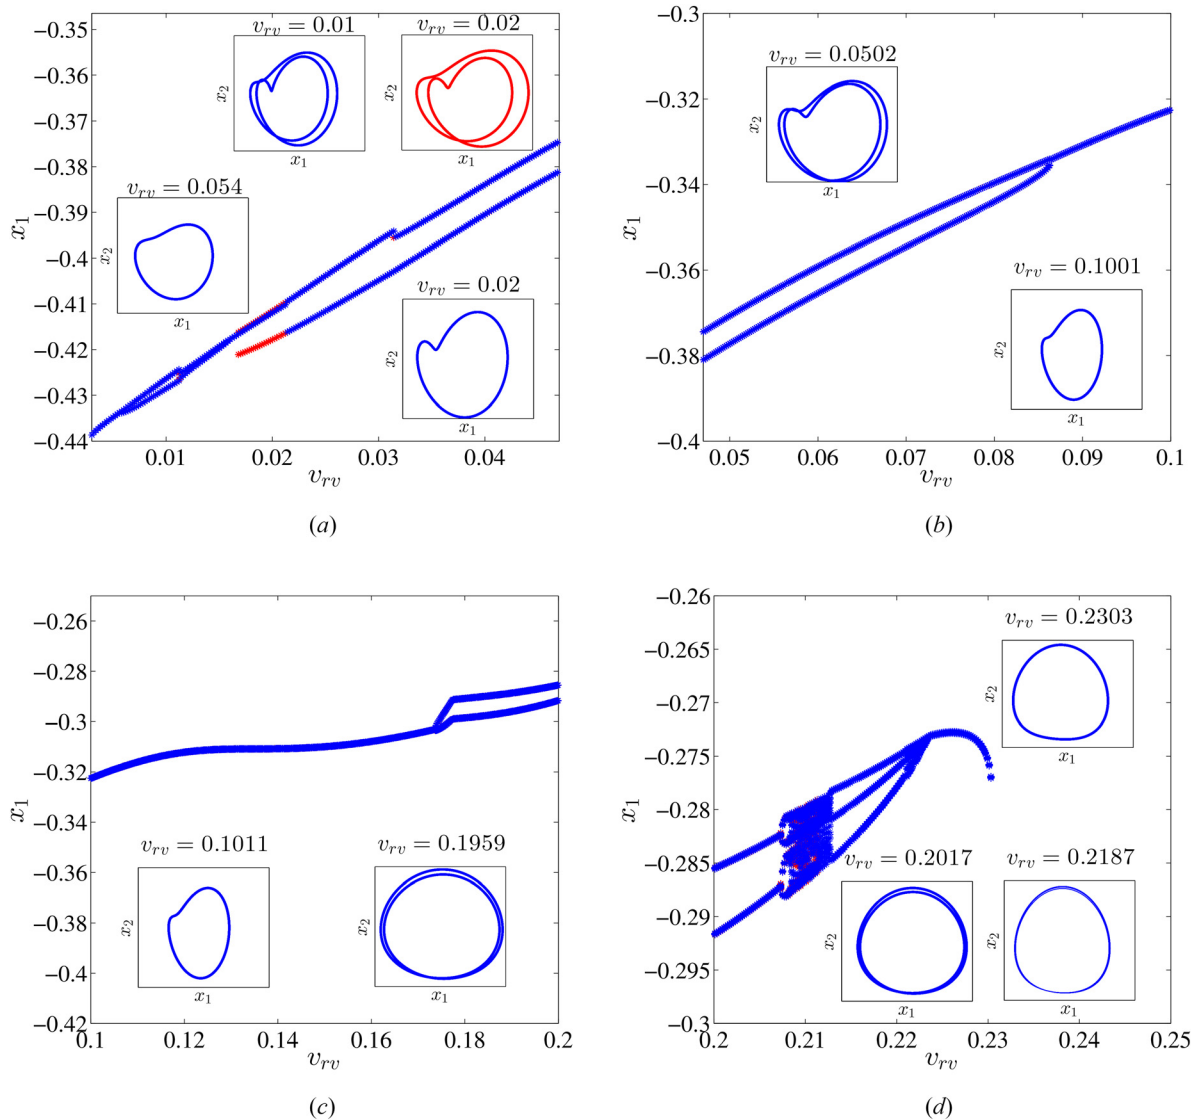

Fig. 11 Zoomed view of Fig. 9(b) for different range of v_{rv}. Other parameters are $\sigma_0 = 110, \sigma_1 = 1.37, \sigma_2 = 0.0823, f_s = 0.44, f_c = 0.35, \kappa = 0.001, a = 2.5, m_r = 2, k_{rq} = 0.2, k_{rc} = 0.2,$ and $k_r = 0.5$.

Fig. 12 Zoomed view of Fig. 10(b) for different range of v_{rv}. Other parameters are $\sigma_0 = 110$, $\sigma_1 = 1.37$, $\sigma_2 = 0.0823$, $f_s = 0.44$, $f_c = 0.35$, $\kappa = 0.001$, $a = 2.5$, $m_r = 2$, and $k_r = 0.5$.

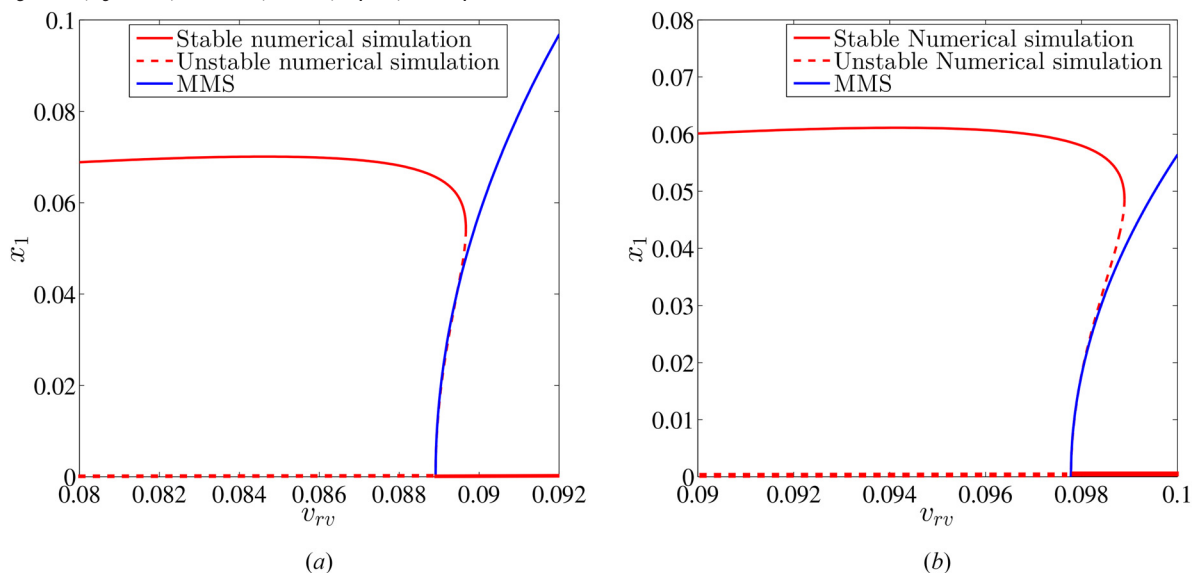

Fig. 13 Comparison of bifurcation diagram from numerical simulation and MMS with v_{rv} as bifurcation parameter for the motion stage (a) with nonlinear FI $\left(k_{rq} = 0.2, k_{rc} = 0.2, \zeta = 0.1\right)$, and (b) with linear FI $\left(k_{rq} = 0, k_{rc} = 0, \zeta = 0.19\right)$. Other parameters are $\sigma_0 = 110$, $\sigma_1 = 1.37$, $\sigma_2 = 0.0823$, $f_s = 0.44$, $f_c = 0.35$, $a = 2.5$, $\kappa = 0.001$, $k_r = 0.5$, $m_r = 2$.

the Hopf point. These results are shown in Figs. 13(a) and 13(b) for MBMS with nonlinear and linear FI, respectively. Since the analysis has been performed close to the Hopf points, we can observe an excellent match between MMS and numerical simulations close to the Hopf point, which further verifies our analytical approach.

6 Conclusion

In this study, we analyzed the linear and nonlinear dynamics of a PD-controlled MBMS with a FI using analytical and numerical methods. Contrary to earlier studies where the nonlinearity in the friction isolator was ignored, the effects of nonlinearity from the friction isolator on the dynamics of the motion stage have been explored in this work. The dynamical effect of friction was captured through the LuGre friction model. A parametric study on the linear stability analysis revealed that compared to the linear friction isolator, the nonlinearity in the friction isolator increases the fixed-points' local stability in the operating parameter space of reference signal and differential gain. This further implied that the system's stability is underestimated when using the linear FI model. The nonlinearity in the FI should be considered in the modeling for a better prediction of steady operating conditions. The nonlinear analysis of MBMS with FI was performed analytically using MMS and numerical simulations. The analytical findings were verified by comparing them against numerical solutions, and a good match was observed. Both analytical and numerical simulations revealed the existence of supercritical and subcritical Hopf bifurcation. Furthermore, the parametric analysis on the criticality of Hopf bifurcation revealed the sensitivities of subcritical and supercritical

Hopf bifurcation regions in terms of the nonlinearities of the friction isolator. On exploring the dynamics of MBMS with nonlinear FI in the unstable regime, we observed period-doubling bifurcations, period-4 solutions, and quasi-periodic solutions.

Finally, these findings suggest that the consideration of nonlinearity in the FI model is an essential step to get an accurate picture of global dynamics of the motion stage with a FI.
